???????????????? ???? ???? ???? ??

1. The first step is to identify the problem and the data available. In this case, the problem is to determine the optimal route for a delivery truck starting from a depot and visiting a set of customers. The data available includes the locations of the depot and customers, the distances between them, and the capacity of the truck.

2. The next step is to formulate the problem as a mathematical model. This can be done using integer programming, where the decision variables represent the route taken by the truck. The objective function is to minimize the total distance traveled, and the constraints include the capacity of the truck and the requirement to visit each customer exactly once.

3. The third step is to solve the mathematical model. This can be done using a solver such as CPLEX or Gurobi. The solver will find the optimal route and the total distance traveled.

4. The fourth step is to implement the solution. This involves creating a program that can take the input data and output the optimal route. This can be done using a programming language such as Python or Java.

5. The final step is to evaluate the solution. This involves comparing the optimal route found by the solver with other routes that might be possible. This can be done by calculating the total distance traveled for each route and comparing them.
