Stress and Strain Fundamentals

Understanding how materials respond to external forces begins with defining and calculating stress and strain:

1. **Stress:** The internal force per unit area within a material, typically expressed in units of Pascals (Pa).
2. **Strain:** The deformation or displacement per unit length caused by applied stress.

Roy R. Craig emphasizes the importance of differentiating between normal and shear stresses, each affecting materials differently.

Stress-Strain Relationships

The book discusses the linear elastic behavior of materials, governed by Hooke's law, and extends into non-linear and plastic deformation regimes.

Analysis of Axial Members

One of the fundamental topics in the mechanics of materials is axial loading, which involves forces applied along the length of a member.

Stress in Axial Members

1. **Normal stress:** Calculated as $\sigma = P/A$, where P is the axial force and A is the cross-sectional area.
2. **Deformation:** Axial elongation or compression, determined by the strain $\epsilon = \Delta L / L_0$.

Design Considerations

1. Material selection based on strength and ductility
2. Safety factors to account for unexpected loads
3. Estimating maximum load capacity

Roy R. Craig emphasizes the importance of understanding these principles for designing reliable load-bearing components.

Bending and Shear in Beams

Beams subjected to transverse loads experience bending moments and shear forces, which are critical for structural analysis.

Bending Stresses

1. Calculated using flexural formula: $\sigma = My/I$, where M is the moment, y is the distance from the neutral axis, and I is the moment of inertia.
2. Neutral axis location and section modulus are key parameters.

Shear Stresses

1. Determined through shear formulas: $\tau = VQ / (It)$, with V being the shear force, Q the statical moment, and t the thickness.
2. Shear flow considerations are important in thin-walled sections.

Combined Bending and Shear

Real-world loads often produce simultaneous bending and shear, requiring combined stress analysis, which Roy R. Craig discusses thoroughly to ensure safety and performance.

Torsion of Circular Shafts

Torsional analysis is essential for rotating machinery and structural components subjected to twisting moments.

Stress Distribution in Torsion

1. Shear stress $\tau = Tr / J$, where T is torque, r is radius, and J is the polar moment of inertia.
2. Stress varies linearly from zero at the center to maximum at the outer surface.

Angle of Twist

1. Calculated using $\theta = TL / (JG)$, with G being the shear modulus.
2. Design aims to limit angular deformation to acceptable levels.

Roy R. Craig discusses the importance of torsion analysis in the design of shafts, couplings, and other rotational components.

Material Behavior and Failure Theories

Understanding how materials behave under various loads is crucial for predicting failure and ensuring safety.

Material Properties

1. Elastic modulus (E)
2. Yield strength
3. Ultimate tensile strength
4. Ductility and toughness

Failure Theories

Roy R. Craig covers several failure criteria used to predict failure in materials under complex loading:

1. **Maximum Normal Stress Theory:** Failure occurs when the maximum normal stress exceeds the material's strength.
2. **Maximum Shear Stress Theory (Tresca):** Failure occurs when the maximum shear stress reaches a critical value.
3. **von Mises Criterion:** More accurate for ductile materials, considering distortional energy.
